## ABSTRACT

This study is interested in the impact of two specific business analytic (BA) resources—accurate manufacturing data and advanced analytics—on a firms' operational performance. The use of advanced analytics, such as mathematical optimization techniques, and the importance of manufacturing data accuracy have long been recognized as potential organizational resources or assets for improving the quality of manufacturing planning and control and of a firms' overall operational performance. This research adopted a contingent resource based theory (RBT), suggesting the moderating and mediating role of fact-based SCM initiatives as complementary resources. This research proposition was tested using Global Manufacturing Research Group (GMRC) survey data and was analyzed using partial least squares/structured equation modeling. The research findings shed light on the critical role of fact-based SCM initiatives as complementary resources, which moderate the impact of data accuracy on manufacturing planning quality and mediate the impact of advanced analytics on operational performance. The implication is that the impact of business analytics for manufacturing is contingent on contexts, specifically, the use of fact-based SCM initiatives such as TQM, JIT, and statistical process control. Moreover, in order for manufacturers to take advantage of the use of data and analytics for better operational performance, complementary resources such as fact-based SCM initiatives must be combined with BA initiatives focusing on data quality and advanced analytics.

## 1. Introduction

There is growing interest in the use of data and advanced analytics for various types of business problems [18,62]. Business Analytics (BA) is an umbrella industry term referring to the application of a broad range of analytical techniques and methods and data-driven analytic methodologies to different business domains. The 2011 annual Gartner survey of IT executives shows that BA is #1 in CIOs' top ten priorities [60]. Anecdotal evidence and industry press suggest a strong positive relationship between the use of BA and organizational and financial performance [15,36]. There has long been interest in BA in manufacturing (and supply chain), where it is expected to make significant contributions [5,14]. Recent studies investigating the role and impact of BA for supply chain management indicate that the use of analytics is positively associated with firm performance [47,61].

This study is interested in the impact of two specific BA resources—accurate manufacturing data and advanced analytics—on manufacturers' operational performance. The use of advanced analytics, such

as mathematical optimization techniques [56,58], and the importance of manufacturing data accuracy [19,35], have been recognized as potential organizational resources or assets for improving the quality of manufacturing planning and control (MPC) and a firms' overall operational performance.

This study takes a contingent resource based theory (RBT) perspective, suggesting that the impact of primary resources on firm performance is contingent upon complementary resources. What resources are primary is context dependent. In the IS literature, for example, ITs are treated as primary resources (e.g., [42]). In the BA contexts, data and analytics are discussed as two most important elements [14,18,47,57]. Thus, advanced analytics and accurate manufacturing data are considered two “primary” resources for the use of BA for manufacturing. Complementary resources are those that are expected to interact with and increase the value of the primary resources (c.f. [21]). Our study considers SCM initiatives or programs as complementary resources. By SCM initiatives, we consider such programs as JIT, TQM, and statistical process control, which are aiming for improving operational efficiency through analytical performance improvement techniques and methods. SCM initiatives are considered “complementary” since they are expected to be interacting with and further increasing the value of manufacturing data and analytics.

The primary research goal is to investigate the role of those complementary resources by testing the mediating and moderating effect of

SCM initiatives in the impact of primary resources (advanced analytics and manufacturing data accuracy) on operational performance. The study uses the data of 533 samples from Global Manufacturing Research Group (GMRG) survey [67], and employs structured equation modeling (SEM)-partial least squares (PLS) to test the premises. In addition, we conduct a multi-group analysis using three subsample groups depending on firm sizes (small, medium, and large).

The study obtains several important findings. First, high data accuracy improves the perceived quality of manufacturing-related plans (e.g., material, inventory, shop floor), which is positively associated with operational performance. Second, the impact of data accuracy is moderated by the use of SCM initiatives. This implies that, while there is much discussion in the literature about the importance of data accuracy, its impact is contingent upon how extensively SCM initiatives, such as JIT, TQM, and statistical process control, are deployed. Third, the use of advanced analytics positively influences operational performance, but its impact is indirect and transmitted through those SCM initiatives. Fourth, a multi-group analysis indicates that there are no significant differences in path coefficients in the PLS model with different sub-sample groups depending on firm sizes.

The research questions and findings are important, since interest in using data and manufacturing analytics for organizational competitiveness, and the relevant investments, is growing among manufacturers. The research findings imply that, in order for manufacturers to take advantage of the use of data and manufacturing analytics for better operational performance, SCM initiatives must be considered an integral part of the firm's investment in BA initiatives.

## 2. Background

### 2.1. A contingent resource-based theory

The resource-based theory (RBT) states that organizational resources or assets vary across firms and they differentiate firms' performance and competitive advantage [2]. RBT has been one of the most prominent and powerful theories in the business literature [3]. In the literature, there are numerous examples of organizational resources, which include enterprise information systems, knowledge representations and processes, and organizational information [33,39,42]. Studies have tried to explain why some resources are effective in certain contexts, but not in others. For example, while IT has been recognized in the literature as an important resource, empirical results have been mixed regarding the impact of IT on firms' performance and competitive advantage [66]. In response, recent studies include contingent variables or complementary resources as necessary elements in their research model [1,6,31]. After reviewing IS research using RBT, Wade and Hulland [66] noted that "resources rarely act alone in creating or sustaining competitive advantage" (p. 123). This leads to paying attention to the role of other resources or complementary resources, which are linked to primary resources in creating sustainable business value. It is expected that there are synergies from primary and complementary resources [43]. For example, Kim et al. [39] considered information resources, analytical and operational capabilities, and human resources as organizational resources, and their study suggested integrating them as a critical factor for CRM success.

As to the role of complementary resources in this synergy-making process, some studies have proposed a moderating effect of complementary resources [66]. In this line, Luo et al. [42] considered IT infrastructure, enterprise information systems, and financial resources as firms' resources for improving organizational capabilities, including operational efficiency. The impact of IT assets (IT infrastructure and enterprise information systems) on organizational capabilities is moderated by financial resources: the positive impact of IT assets on organizational capabilities is stronger when firms possess greater financial assets. In addition, mediation has been suggested as another potential role of complementary resources [41]. For example, IT and organizational

structure as resources positively affect new product performance. This process is translated through a mediator or a contingent variable, such as cross-functional integration [11]. Thus, an RBT-based research model could benefit from considering contingent variables as potential moderators and/or mediators.

### 2.2. A contingent RBT for analytics

By applying the concept of contingent RBT into studying the role of business analytics, this study focuses on the effects of data accuracy and advanced analytics. When a contingent RBT is applied in studying the role of business analytics for manufacturing, the focus is on the use of advanced analytics and manufacturing data accuracy. Business analytics is defined as "the extensive use of data, statistical and quantitative analysis, explanatory and predictive models, and fact-based management to drive decision and actions" [15]. Thus, data accuracy and advanced analytics could be two primary resources. The value of quality data is well recognized in the literature [52]. "You can't be analytical without *data*, and you can't be really good at analytics without really good *data*" (emphasis added) [13]. There is much promise from using advanced analytics (e.g., mathematical optimization) for manufacturing firms [10,47,58]. This would result in a research model testing the direct impact of data accuracy and advanced analytics on manufacturers' operational performance. However, this approach may find it difficult to explain why some resources are more or less effective in certain situations.

Thus, our research model considers a set of complementary resources, which represent SCM initiatives, such as JIT, TQM, and statistical process control. These increasingly popular SCM programs are examples of fact-based management initiatives in manufacturing firms [37,38,45]. The premise of a contingent RBT for business analytics is that the role of such analytic resources as data accuracy and advanced analytics is contingent upon a set of complementary resources. It is expected that when accurate data and advanced analytics are complemented with fact-based SCM initiatives, the value of accurate data would be realized through improved manufacturing planning quality, and the use of advanced analytics can achieve the increase in operational efficiency.

## 3. Research model

Our research model examines the role of moderation and mediation in the impact of accurate manufacturing data and advanced analytics in operational efficiency. First, a moderator is defined as a variable that "affects the direction and/or strength of the relation between an independent or predictor variable and a dependent or criterion variable" [4]. The idea of moderating effect is related to the premise of contingency theory that the effect of X variable on Y variable can be stronger or weaker, depending on other factors, which are moderators. A moderator influences the strength of the impact of X on Y [32]. Thus, it addresses "when" the effect occurs [4].

For example, the impact of information content quality and information access quality on the use of information in business processes is contingent upon analytical decision-making culture, which is a moderator [51]. Similarly, the higher the IS support and business process orientations in an organization, the stronger the impact of analytics on organizational performance [61]. The effect of supply chain analytic IT on organizational performance is contingent upon environmental uncertainty [16].

In the literature, quality data are considered to be important organizational resources or assets [10,52], impacting organizational performance [24,27]. Poor data quality is costly, having consequences on decision making and operation [53]. In SCM contexts, data is the input to the MPC process. Thus, poor data, which is often characterized by lack of information management and of advanced planning IT, can have far-reaching negative impacts on manufacturing planning [28]. On the

other hand, accurate data is necessary for effective decision making and planning in manufacturing [19,24,29,50]. This leads us to posit that quality data is positively associated with the quality of manufacturing planning. Manufacturing planning (and scheduling) significantly influences operational performance [17,63]. Thus, we propose:

**Hypothesis 1.** Data accuracy improves manufacturing planning quality, which is positively related to operational performance.

We also believe that the positive effect of quality data on manufacturing planning is strengthened when SCM initiatives are combined. Data and business processes are closely connected: processes use existing data and also create new data [52]. Thus, there is an interactional effect of data and process improvement on manufacturing planning. SCM initiatives (e.g., statistical process control) are fact-based, analytical techniques and tools focusing on manufacturing process improvement. This leads us to posit that SCM initiatives can be an important contingent variable when firms exploit their data for operation. This indicates the moderating role of fact-based SCM initiatives or programs. On this basis, our second hypothesis is:

**Hypothesis 2.** SCM initiatives moderate the impact of data accuracy on manufacturing planning quality.

In addition to the moderating effect, we also expect the role of mediation for those SCM initiatives or programs. “A given variable may be said to function as a mediator to the extent that it accounts for the relation between” X and Y [4]. A mediator (M) explains “how” or “why” the effect of X occurs on Y [4]. In other words, a mediator is “a pathway for the effect of a predictor on an outcome” [34].

Testing the existence of mediating effect only makes sense when there is the effect of X on Y. When the condition is met, then additional criterion need to be tested for the mediating effect to exist. With the inclusion of a mediator variable (M) in the model, it needs to be proven that X affects M and M affects Y. Finally, the effect of X on Y, when M is added into the model, should be zero or significantly weakened.

There has been a long tradition of research on the use of analytical tools and techniques (e.g., mathematical optimization) for manufacturing [56]. Studies have seen the potential of advanced analytics to improve operational performance. Davenport et al. [14,15] have described several areas (e.g., inventory management, network management) where advanced analytics can benefit companies. Trkman et al. [61] reported that analytics can support supply chain processes such as plan, source, make, and deliver. In this line of research, Sharma et al. [57] suggested that there may be an indirect relationship between analytics and performance, noting that analytics enables manufacturers “to apply resources to undertake actions to deliver performance gains and competitive advantage” (p. 193). The authors also noted the use of analytics in quality and process improvement [59], which enhances operational performance.

On this basis and from a contingent RBT perspective, we expect that the impact of advanced analytics on operational performance is mediated through fact-based SCM initiatives. SCM initiatives, such as TQM and statistical process control, are fact-based or analytical methodologies for process and quality improvement. The implementation and

effectiveness of those methodologies do not occur in a vacuum. Instead, among others, organizations' analytical capability is considered an enabling condition for the effective implementation of those methodologies.

**Hypothesis 3.** The positive effect of advanced analytics on operational performance is mediated through SCM initiatives.

A conceptual research model summarizing from the above discussion of moderating effect and mediating effect is presented in Fig. 1. In addition to these three hypotheses based on the review of previous studies, our research will also explore the existence of other possible relationships moderated and mediated through SCM initiatives.<sup>1</sup>

## 4. Research methodology

### 4.1. Data source

The data were a sub-sample of the Round IV GMRG data collection effort. The Global Manufacturing Research Group (GMRG) ([www.gmrg.org](http://www.gmrg.org)) is an international community of researchers studying the improvement of manufacturing supply chains worldwide. The GMRG consists of leading international academic researchers from over 20 countries. These researchers developed the GMRG survey instrument to understand manufacturing and supply chain practices around the world. This survey instrument facilitates a global comparison of the effectiveness of manufacturing and supply chain practices [67]. Since 1985, the GMRG has completed three rounds of the worldwide survey and is currently completing the fourth round. The survey questionnaires for all countries were translated and back-translated by several academic researchers.

This study uses the data from the Round 4.0 GMRG Survey, with 533 samples from 15 countries and 14 industry classifications (See Appendix Table A for distribution statistics). The GMRG questionnaire consists of two parts [67]. The first part is the background section on company demographics, manufacturing practices, competitive goals, and internal performance. The second part contains four optional modules addressing specific management issues: Manufacturing Information Systems (MIS), Outsourcing, Purchasing, and Forecasting. Among them, the background section, the MIS module, and the Outsourcing module provide specific information pertaining to the research objectives of this study, such as data accuracy, data analysis, quality of manufacturing planning, operational performance, organizational processes, and business analytics. The survey questionnaire was previously validated in many studies published in top journals, including the *Journal of Operations Management*, *Decision Sciences*, among others. The breadth and depth of the data indicate the generalizability of the results [9,64], and there have been many studies using this data set, published in top-tier journals.

### 4.2. Constructs

The research design includes five constructs. Data accuracy (DA) and advanced analytics (AA) are constructed related to two primary resources of business analytics for manufacturing. SCM initiatives (SCI) serve as a construct of moderator and mediator representing complementary resources. Manufacturing planning quality (MPQ) and operational performance (OP) are two dependent constructs (see Appendix B for further details).

#### 4.2.1. Data accuracy (DA)

Data is key for manufacturing-related decision making and planning [55]. There are diverse sets of production and supply chain planning

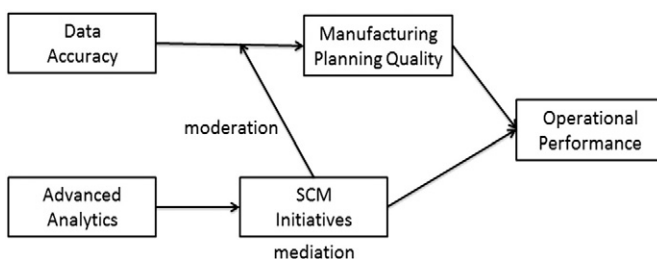

Fig. 1. A conceptual research model.

<sup>1</sup> We thank an anonymous reviewer for suggesting this. We acknowledge that this has led to offering additional insights, which are reported in Sections 5.2 and 6.

data required for planning, including inventory records [19]. Data accuracy is measured by survey assessed accuracy level of three types of data: inventory records, plants' bills of material, and routings.

#### 4.2.2. Advanced analytics (AA)

This AA construct is a measure for how analytical a firm becomes in manufacturing-related decisions. There are different measurements for assessing the level of analytical capabilities of a manufacturer in previous studies [61]. For example, Davis-Sramek et al. [16] used the level of analytical IT use. We consider three methods as primary ways for data analysis: experience, statistical methods, and mathematical optimization. These three methods represent three levels of advanced analytics (experience as basic; statistical methods as intermediate; mathematical optimization as advanced).

#### 4.2.3. SCM initiatives or programs (SCI)

The literature shows that manufacturers have adopted diverse process and quality programs to improve operational performance. These programs tend to be fact-based, in that manufacturing data are used for performance evaluation and control [37,38,45]. In this study, SCI is represented by the extent of organizational investment in three such practices: just in time, total quality management, and statistical process control.

#### 4.2.4. Manufacturing planning quality (MPQ)

The quality of manufacturing planning is important for improving operational performance. Perceived quality of manufacturing planning is used in this study. MPQ is measured by the extent of satisfaction on five types of manufacturing planning: material planning, inventory control, labor planning, shop floor control, and cost planning [65].

#### 4.2.5. Operational performance (OP)

OP represents manufacturers' operational performance. Manufacturers have used diverse measurements for operational performance [63]. We use five performance-related measurements: order fulfillment, delivery as promised, delivery flexibility, and flexibility to change product mix and flexibility to change output volume.

### 5. Model analysis

Business analytics for manufacturing is increasingly becoming an important practice in industry and a research topic in academia. There are two primary resources related to this business practice: accurate data and advanced analytics. This research takes a contingent RBT perspective on the effect of these resources on operational performance. The proposed approach focuses on the moderating and mediating roles of SCM initiatives or programs. Thus, this research is exploratory, rather than confirmatory in nature, and focuses on understanding the relationships between business analytics-related resources and manufacturing operational performance. Partial Least Squares (PLS) is suitable for this type of research [25,30,49]. WarpPLS software was used in this model analysis. Below, we report evaluation of individual measurements and evaluation of the overall PLS model.

#### 5.1. Measure evaluation

For reliability, we assess composite reliability and combined item loading scores. The composite reliability coefficients of all constructs (Table 1) are greater than 0.80, indicating acceptable reliability [23,46]. Combined loadings for all indicators are greater than 0.70 and significant at the level of 0.001 (Table 1).

To assess the validity of each construct, we use the square root of the average variance extracted (AVE). The AVE values for all constructs

**Table 1**  
Composite reliability and average variances extracted (AVE).

Composite reliability	AVE		DA	MPQ	SCI	AA	OP
0.915	0.783	<b>DA</b>	<b>0.885</b>	0.147	0.000	0.064	0.063
0.910	0.670	<b>MPQ</b>	0.147	<b>0.819</b>	0.339	0.238	0.212
0.819	0.602	<b>SCI</b>	0.000	0.339	<b>0.776</b>	0.252	0.313
0.891	0.731	<b>AA</b>	0.064	0.238	0.252	<b>0.855</b>	0.069
0.903	0.651	<b>OP</b>	0.063	0.212	0.313	0.069	<b>0.807</b>

Note: Square roots of average variances extracted (AVE's) shown on diagonal.

are greater than 0.50, indicating convergent validity at the construct level. Each indicator's loading is higher than its cross loadings [12,30] (Table 2) and the square root of every AVE is much higher than any correlation between the construct and other constructs [26] (Table 1), indicating discriminant validity.

#### 5.2. Evaluation of the PLS-SEM model

First, we assess the moderating effect of SCM initiatives between data accuracy (DA) and manufacturing planning quality (MPQ). PLS analysis shows that DA is positively associated with MPQ and there are moderating effects ( $\beta = 0.21$   $p = 0.01$ ) of fact-based SCM initiatives (SCI) such as TQM, JIT, and statistical process control (Fig. 2). This confirms the role of SCI as a moderator, but the effect size seems small as indicated by relatively low R-squares. After this confirmation, we extended our analysis to see if the moderation of SCI is, in fact, "mediated moderation". Mediated moderation takes places when four variables are interacting through moderation and mediation in that the interaction effect of an independent variable and a moderator on the dependent variable is through a mediator [8,44]. The result indicates the presence of a mediated moderation. That is, the interacting effect of data accuracy and SCI initiatives is transmitted to operational performance through manufacturing planning quality.

Second, studying the mediating effect requires two separate models. One model is designed with only two constructs: advanced analytics (AA) and operational performance (OP). The PLS analysis shows that there is a significant relationship ( $\beta = 0.12$   $p = 0.04$ ) between advanced analytics and operational performance at the level of 0.05. With this finding, which validates the further analysis for mediation, another model is developed with a third construct (SCI). The analysis

**Table 2**  
Loadings and cross-loadings.

Item	AA	DA	MPQ	SCI	OP	P value
AA_1	<b>0.850</b>	0.010	0.004	0.006	-0.087	<0.001
AA_2	<b>0.871</b>	-0.014	0.007	0.025	0.028	<0.001
AA_3	<b>0.843</b>	0.004	-0.011	-0.032	0.059	<0.001

DA_3	0.058	<b>0.802</b>	-0.013	0.112	0.010	<0.001
MPQ_1	-0.039	0.065	<b>0.820</b>	0.009	0.010	<0.001
MPQ_2	-0.024	0.042	<b>0.810</b>	-0.027	0.044	<0.001
MPQ_3	0.055	-0.012	<b>0.840</b>	-0.078	0.002	<0.001
MPQ_4	0.036	-0.033	<b>0.818</b>	0.026	-0.042	<0.001
MPQ_5	-0.031	-0.062	<b>0.805</b>	0.073	-0.014	<0.001
SCI_1	-0.087	-0.035	0.053	<b>0.795</b>	0.072	<0.001
SCI_2	0.130	0.100	-0.068	<b>0.784</b>	-0.107	<0.001
SCI_3	-0.044	-0.067	0.015	<b>0.747</b>	0.036	<0.001
OP_1	-0.008	-0.072	0.034	0.052	<b>0.805</b>	<0.001
OP_2	0.018	-0.077	0.055	0.010	<b>0.785</b>	<0.001
OP_3	-0.021	0.017	-0.026	-0.048	<b>0.853</b>	<0.001
OP_4	0.010	0.072	-0.039	0.049	<b>0.826</b>	<0.001
OP_5	0.002	0.059	-0.021	-0.065	<b>0.761</b>	<0.001

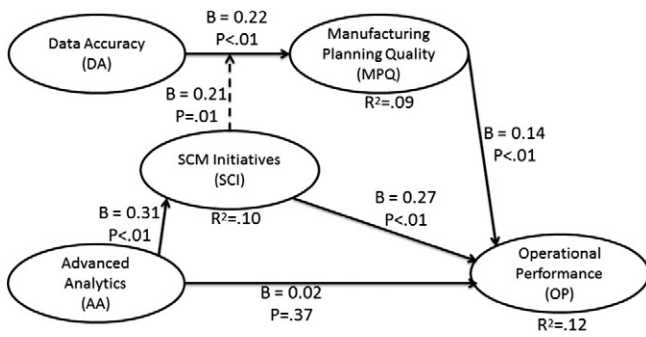

Fig. 2. The complete results.

indicates that when SCI is added as a mediator between AA and OP, the direct impact of AA on OP becomes non-significant ( $\beta = 0.02$ ,  $p = 0.37$ ) and SCI plays the role of mediator between the two constructs. We also tested the mediating impact of SCI using the Sobel test and through the estimation of indirect effects [40]. The outcomes confirm the mediating role of SCI.

Fig. 2 shows the complete PLS model and its results. Table 3 presents the results of testing three hypotheses. In summary, data accuracy increases manufacturing planning quality, which subsequently improves manufacturing operational performance. There is no direct relationship between data accuracy and operational performance. Additionally, the positive impact of data accuracy on planning quality is greater when resources such as SCM initiatives are invested. Advanced analytics makes a positive contribution to operational performance. But its impact is indirect, through SCM initiatives as a mediator.

We continued our analysis using a multi-group analysis. For this, we divided the data into subsamples depending company size. Our multi-group analysis focused on three subsamples—(1) small firm size, (2) medium firm size and (3) large firm size. The sample sizes are 115, 206, and 212 respectively (see Appendix A). Our analysis produced a t-statistic and p values using the sample sizes, coefficients of the relationships, and standard errors (see Table 4). The results of t-statistics and p values indicate that there is no statistical significance of difference in these three groups.

Next, we extended our analysis into exploring the existence of other possible moderated or mediated relationships among the constructs through SCM initiatives. We specifically looked at the significance of the following moderated and mediated relationships in our analysis:

- #1 SCM initiatives (SCI) moderate the impact of data accuracy (DA) on operational performance (OP).
- #2 SCM initiatives moderate the impact of advanced analytics (AA) on operational performance.
- #3 SCM initiatives moderate the impact of advanced analytics on manufacturing planning quality.

Table 3  
The results of testing hypotheses.

Hypothesis 1: Data accuracy improves manufacturing planning quality, which is positively related to operational performance.	Supported
Hypothesis 2: SCM initiatives moderate the impact of data accuracy on manufacturing planning quality.	Supported
Hypothesis 3: The positive effect of advanced analytics on operational performance is mediated through SCM initiatives.	Supported

Table 4  
The results of a multi-group analysis depending on firm size.

Relationships	Small vs. medium size		Small vs. large size		Medium vs. large size	
	t-statistic	p	t-statistic	p	t-statistic	p
AA-OP	0.277	0.782	1.002	0.317	1.419	0.157
AA-SCI	0.070	0.944	0.062	0.951	0.010	0.992
DA-MPQ	0.886	0.376	0.803	0.422	0.227	0.821
SCI-OP	0.645	0.519	0.058	0.954	0.688	0.492
MPQ-OP	1.591	0.113	1.756	0.080	0.827	0.409
SCI*DA	0.976	0.330	0.301	0.763	1.031	0.303

- #4 The effect of advanced analytics on manufacturing planning quality (MPQ) is mediated through SCM initiatives.
- #5 The effect of data accuracy on operational performance is mediated through SCM initiatives.
- #6 The effect of data accuracy on manufacturing planning quality is mediated through SCM initiatives.

To test these relationships, we expanded the original research model by including 6 additional relationships. The full dataset (533 samples) was used in this analysis. The results of testing this expanded model show that only the mediating role of SCM initiatives in the impact of advanced analytics on manufacturing planning quality (#4) is found to be statistically significant. AA is positively associated with MPQ ( $\beta = 0.24$ ,  $p < 0.01$ ). When SCI is added as a mediator, the relationship between AA and MPQ becomes weaker ( $\beta = 0.13$ ,  $p < 0.01$ ), while the relationships (AA → SCI and SCI → MPQ) are found to be statistically significant. On the other hand, none of the other relationships (#1, #2, #3, #5, and #6) were found to be statistically significant.

### 6. Discussion and implications

There is an increasing interest in the extensive use of data and analytical techniques and tools for business, broadly known as business analytics. Recent studies have suggested the business value of data and analytics for manufacturing [14,47,48,61]. Our research supports that accurate manufacturing data and advanced analytics could be valuable resources for creating business value, specifically improving manufacturers' operational performance.

First, data is considered important for business [52] and a key building block of business analytics for manufacturing. Quality data is also an indicator of firms' analytical maturity [51]. This study finds that accurate manufacturing data can increase the quality of manufacturing planning. This confirms findings of previous studies that manufacturing data and their quality are important for SCM [10,35], and planning quality positively contributes to operational performance [17,63]. In addition, our findings shed light on the moderating role of SCM initiatives. When manufacturers combine accurate data with complementary resources, such as TQM, JIT, and statistical process control, they are able to enhance the business value of accurate data for manufacturing planning quality. Our extended analysis also indicates that there is mediated moderation. That is, for the manufacturers with high SCM initiatives, data accuracy leads to increased manufacturing planning quality, which subsequently improves operational performance.

Second, in recent years the use of advanced analytics has been echoed in academic literature and industry press. Previous studies suggest that firms can create business value from the adoption of advanced analytics [7,13]. Some have found that there is a direct positive relationship between advanced analytics and operational performance. For example, the use of analytics for SCM processes such as plan, source, make, and delivery, was found to be positively associated with

operational performance [61]. However, our finding indicates that there could also be an indirect relationship between analytics and organizational performance. Specifically, the positive impact of advanced analytics on operational performance is fully mediated through the adoption of fact-based SCM initiatives. When SCM initiatives (SCI) were included in the PLS model, the relationship between advanced analytics (AA) and operational performance (OP) dropped to almost zero. This explains how and why advanced analytics positively impacts operational performance. The use of advanced analytics as the primary way of determining manufacturing data is likely to increase the adoption of fact-based or analytical SCM programs (e.g., JIT, statistical process control). In turn, these practices make a positive impact on operational performance [37,54].

According to multi-group analysis, which was reported earlier in Section 5, there are no statistically significant differences in the path coefficients regardless of firm size. In addition, our extended analysis of testing additional moderated and mediated relationships through SCM initiatives (SCI) shows that SCI carries the mediating role between advanced analytics (AA) and manufacturing planning quality (MPQ). This suggests that the use of advanced analytics positively contributes to the planning quality and its impact is partially transmitted through SCM initiatives.

The findings from this research can be useful for practice and research as the volume of manufacturing-related data and the power of analytical tools are growing at a high speed. For practice, our research findings imply that BA projects for manufacturing must consider the investment, not only in primary resources such as data (and data quality) and advanced analytics (e.g., mathematical optimization techniques), but also in complementary resources, specifically, analytical performance management programs. These programs need to be combined with quality data and advanced analytical capabilities in an integrated way. Without those complementary resources, the promises of such primary resources as quality data and advanced analytics would not be realized.

For research, in investigating the impact of business analytics most studies have expected the direct impact of data and analytical capabilities on operational and/or financial performance. Our research findings reveal the possibility of complementary resources to play a mediating role, thereby suggesting that the indirect, rather than direct, relationship is a more likely explanation as to the impact of business analytics on manufacturers' operational performance. Ignoring important mediators such as SCM initiatives could lead to a potentially misleading conclusion that the use of advanced analytics alone creates business value and improves operational performance. This further suggests the need of a contingent perspective for studying the value of business analytics, specifically, for manufacturing (and SCM).

Finally, that there is the moderating effect of complementary resources in the impact of accurate data on manufacturing planning quality seems to indicate that it would be possible for manufacturers to consider configuration strategies. For example, the investment in data and IT infrastructure for quality data alone would be an efficient business decision for manufacturers in stable business environments. In contrast, those in dynamic environments would choose to deploy fact-based SCM initiatives along with the investment for accurate data. This further demands the use of contingency (or configuration) theory [20,22] in studying the value of business analytics.

## 7. Conclusion

As there is a growing interest in the deployment of business analytics (BA) for manufacturing, it is imperative for firms to understand business values of such investment and for prescribing ways to extract benefits of BA in practice. This study has attempted to address these issues by investigating the impact of two primary BA resources: accurate data and advanced analytics. The research adopted a contingent resource based theory (RBT), suggesting the moderating and mediating

role of fact-based SCM initiatives as complementary resources. This research design was tested using Global Manufacturing Research Group (GMRG) survey data and PLS-SEM methods.

The research findings could shed light on the critical role of SCM initiatives as complementary resources, which moderate the impact of data accuracy on manufacturing planning quality and mediate the impact of advanced analytics on operational performance. This indicates that the impact of business analytics for manufacturing is contingent on contexts, specifically, the use of fact-based SCM programs such as TQM, JIT, and statistical process control. These findings imply that, in order for manufacturers to take advantage of the use of data and analytics for better operational performance, complementary resources, such as fact-based SCM initiatives, must be combined with BA initiatives focusing on data quality and analytics. This suggests that future research on BA impact and benefits could further benefit from contingency (or configuration) theory.

In this regard, future studies could benefit from case research in gaining greater understanding of technological and organizational contexts (or contingencies) where business analytics are deployed to improve operational performance. Our research model did not include a control variable(s). Future research could consider such contexts as environmental uncertainty and supply chain complexity as control variables. The present study has used the GRMG survey data to explore a relatively new topic, business analytics for manufacturing operation. We believe it will be a fruitful endeavor to extend this line of research using a first-hand dataset, entirely designed for this increasingly important subject in business.

## Appendix A Distribution of industries and firm size

(a) Firm size					
Size	Frequency		Percentage		
(1) ≤50 employees	115		21.6%		
(2) 51–250 employees	206		38.6%		
(3) ≥251 employees	212		39.7%		
Total	533		100.0%		
(b) Industry					
Industry	Freq.	Percent	Industry	Freq.	Percent
Food and kindred products	29	5.4%	Rubber and miscellaneous plastics products	19	3.6%
Textile mill products	16	3.0%	Primary metal industries	5	0.9%
Apparel and other finished products	9	1.7%	Fabricated metal products	60	11.3%
Leather and leather products	5	0.9%	Industrial and commercial machinery	70	13.1%
Lumber and wood products, except furniture	7	1.3%	Electronic and other electrical equipment	116	21.8%
Paper and allied products	15	2.8%	Measuring, analyzing, and controlling instruments	12	2.3%
Printing, publishing, and allied industries	5	0.9%	Manufacture of motor vehicles, trailers and semi-trailers	7	1.3%
Petroleum refining and related industries	3	0.6%	Manufacture of other transport equipment	6	1.1%
Chemical and allied products	14	2.6%	Furniture and fixtures	13	2.4%
Miscellaneous manufacturing industries	27	5.1%	Stone, clay, glass, and concrete products	11	2.1%
Not reported	84	15.8%	<b>Total</b>	<b>533</b>	<b>100.0%</b>

## Appendix B Detailed information on constructs

Construct: DA (data accuracy)	Mean	S.D
1) How accurate are the plant's inventory records?	0.809	0.317
2) How accurate are the plant's bills of material?	0.810	0.323
3) How accurate are routings?	0.697	0.398
Construct: AA (advanced analytics)	Mean	S.D
1) What is the primary way of determining manufacturing batch sizes?	1.747	0.767
2) What is the primary way of determining lead times and routings	1.726	0.751
3) What is the primary way of determining safety stocks and safety lead times?	1.741	0.744
1: experience/2: Statistical methods/3: Mathematical optimization		
Construct: SCI (SCM initiatives)	Mean	S.D
1) Extent of invested resources in TQM	4.595	1.689
2) Extent of invested resources in statistical process control	3.835	1.805
3) Extent of invested resources in JIT	3.938	1.776
1: not at all – 7: to a great extent		
Construct: MPQ (manufacturing planning quality)	Mean	S.D
To what extent are you satisfied with your current:		
1) Material planning	4.678	1.517
2) Inventory control	4.784	1.539
3) Labor planning	4.296	1.527
4) Shop floor control	4.495	1.508
5) Cost planning	4.670	1.516
1: very dissatisfied – 7: very satisfied		
Construct: OP (operational performance)	Mean	S.D
Compare the performance with your major competitors		
1) Order fulfillment	5.268	1.221
2) Delivery as promised	5.253	1.180
3) Delivery flexibility	5.356	1.147
4) Flexibility to change output volume	5.120	1.208
5) Flexibility to change product mix	5.094	1.252
1: far worse – 7: far better

**Bongsug (Kevin) Chae** is an Associate Professor in Information & Operations Management at Kansas State University. He has published papers in such areas as business analytics, social media analytics, IT-enabled service innovation, supply chain analytics, and data mining. He has made presentations in conferences and global companies, primarily on the topic of business analytics and intelligence, supply chain analytics, and service innovation. He received the Ralph Reitz Teaching Award and was nominated for numerous teaching awards at Kansas State University.

**Chenlung Yang** is a professor in the department of technology management at Chung Hua University, Taiwan. His research is in such areas as supply chain management, decision support techniques, and service operations. His work has been published in journals, including *International Journal of Operations & Production Management*, *Omega*, *Journal of Supply Chain Management*, *International Journal of Production Research*, *Journal of Cleaner Production* and *International Journal of Production Economics*.

**David L. Olson** is the James & H.K. Stuart Professor in MIS and Chancellor's Professor at the University of Nebraska. He has published research in over 100 refereed journal articles, primarily on the topic of multiple objective decision-making and information technology. He teaches in the management information systems, management science, and operations management areas. He has authored 18 books, to include *Decision Aids for Selection Problems*, *Introduction to Information Systems Project Management*, *Managerial Issues of Enterprise Resource Planning Systems*, *Supply Chain Risk Management*, and *Supply Chain Information Technology*. Additionally, he has co-authored the books *Introduction to Business Data Mining*, *Enterprise Risk Management*, *Advanced Data Mining Techniques*, *New Frontiers in Enterprise Risk Management*, *Enterprise Information Systems*, and *Enterprise Risk Management Models*. He is an associate editor of *Service Business* and co-editor in chief of *International Journal of Services Sciences*. He has made over 100 presentations at international and national conferences on research topics. He is a member of the Decision Sciences Institute, the Institute for Operations Research and Management Sciences, and the Multiple Criteria Decision Making Society. He was a Lowry Mays endowed Professor at Texas A&M University from 1999 to 2001. He was named the Raymond E. Miles Distinguished Scholar award for 2002, and was a James C. and Rhonda Seacrest Fellow from 2005 to 2006. He was named Best Enterprise Information Systems Educator by IFIP in 2006. He is a Fellow of the Decision Sciences Institute.

**Chwen Sheu** is the Paul Edgerley Chair professor in the department of management at Kansas State University. He has published research in over 60 referred journal articles, primarily on the topic of supply chain management, decision support systems, and operations management. He is the recipient of various teaching and research awards from international organizations and Kansas State University.
